

# Block Cipher Operation

Raj Jain

Washington University in Saint Louis  
Saint Louis, MO 63130

[Jain@cse.wustl.edu](mailto:Jain@cse.wustl.edu)

Audio/Video recordings of this lecture are available at:

<http://www.cse.wustl.edu/~jain/cse571-11/>

1. Double DES, Triple DES, DES-X
2. Encryption Modes for long messages:
  1. Electronic Code Book (ECB)
  2. Cipher Block Chaining (CBC)
  3. Cipher Feedback (CFB)
  4. Output Feedback (OFB)
  5. Counter (CTR) Mode
  6. XTS-AES Mode for Block-oriented Storage Devices

These slides are based partly on Lawrie Brown's slides supplied with William Stallings's book "Cryptography and Network Security: Principles and Practice," 5<sup>th</sup> Ed, 2011.

# Double-DES

□  $C = E_{K2}(E_{K1}(P))$

□ **Meet-in-the-middle attack**

- Developed by Diffie and Hellman in 1977
- Can be used to attack any composition of 2 functions

$$X = E_{K1}(P) = D_{K2}(C)$$

- Attack by encrypting P with all  $2^{56}$  keys and storing
- Then decrypt C with keys and match X value
- Verify with one more pair
- Takes max of  $O(2^{56})$  steps  $\Rightarrow$  Total  $2^{57}$  operations

□ Only twice as secure as single DES

# Triple-DES

- ❑ Use DES 3 times:  $C = E_{K_3} (D_{K_2} (E_{K_1} (P) ) )$
- ❑ E-D-E provides the same level of security as E-E-E
- ❑ E-D-E sequence is used for compatibility with legacy
  - $K_1=K_2=K_3 \Rightarrow$  DES
- ❑ PGP and S/MIME use this 3 key version
- ❑ Provides 112 bits of security
- ❑ Two keys with E-D-E sequence
  - $C = E_{K_1} (D_{K_2} (E_{K_1} (P) ) )$
  - Standardized in ANSI X9.17 & ISO8732
  - No current known practical attacks
  - Several proposed impractical attacks might become basis of future attacks

# DES-X

- ❑ Proposed by Ron Rivest in May 1984
- ❑ XOR 64-bit key  $K_1$  before DES encryption and xor another 64-bit key  $K_2$  after encryption

$$C = K_2 \oplus E_K(P \oplus K_1)$$

- ❑ Total Key size =  $56+64+64 = 184$  bits  
But increases security by 88 to 119 bits

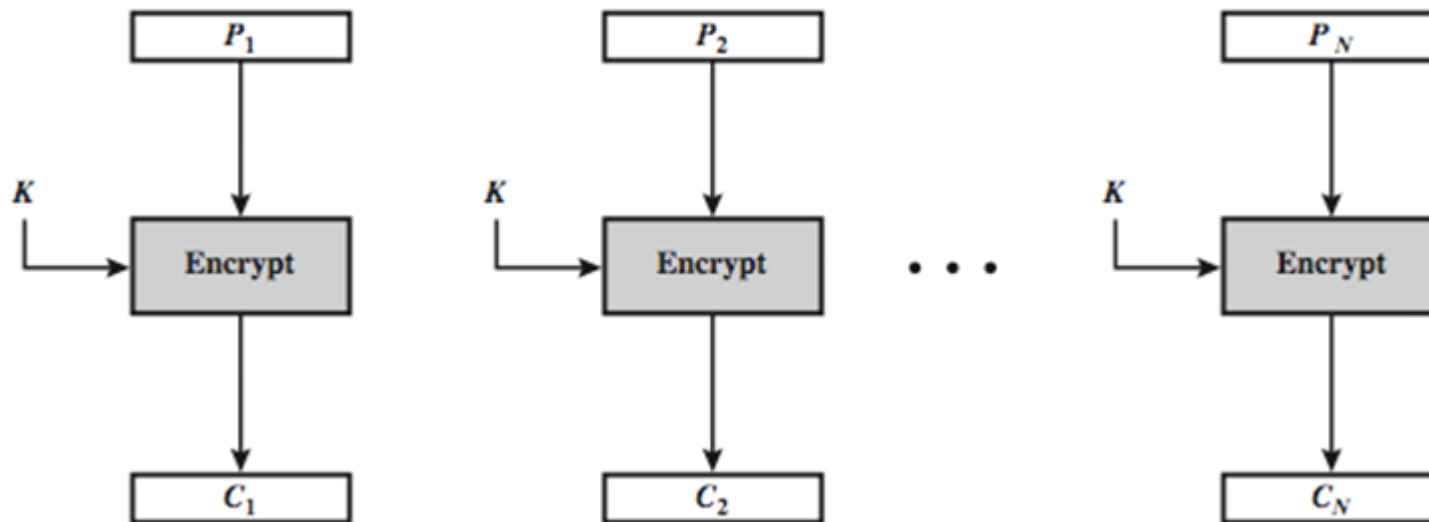

Ref: <http://en.wikipedia.org/wiki/DESX>

# Electronic Codebook Book (ECB)

- ❑ How to encode multiple blocks of a long message?
- ❑ Each block is encoded independently of the others

$$C_i = E_K(P_i)$$

- ❑ Each block is substituted like a codebook, hence name.

# ECB Limitations

- ❑ Using the same key on multiple blocks makes it easier to break
- ❑ Identical Plaintext Identical Ciphertext  
Does not change pattern:

Original

ECB

Better

- ❑ NIST SP 800-38A defines 5 modes **that** can be used with any block cipher

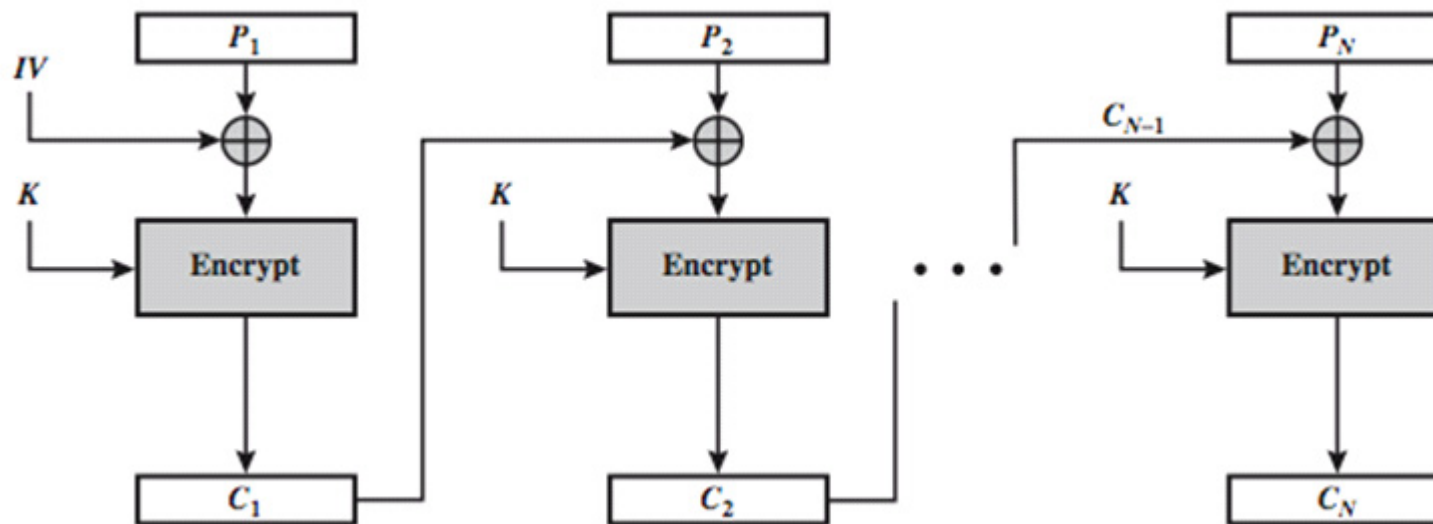

Ref: [http://en.wikipedia.org/wiki/Modes\\_of\\_operation](http://en.wikipedia.org/wiki/Modes_of_operation)

# Cipher Block Chaining (CBC)

- ❑ Add random numbers before encrypting
- ❑ Previous cipher blocks is chained with current plaintext block
- ❑ Use an Initial Vector (IV) to start process

$$C_i = E_K (P_i \text{ XOR } C_{i-1})$$

$$C_1 = IV$$

## Advantages and Limitations of CBC

- ❑ Any change to a block affects all following ciphertext blocks
- ❑ Need **Initialization Vector (IV)**
  - Must be known to sender & receiver
  - If sent in clear, attacker can change bits of first block, and change IV to compensate
  - Hence IV must either be a fixed value, e.g., in Electronic Funds Transfers at Point of Sale (EFTPOS)
  - Or must be sent encrypted in ECB mode before rest of message

- ❑ Sequential implementation <sup>69</sup> Cannot be parallelized

# Message Padding

- ❑ Last block may be shorter than others  $\Rightarrow$  Pad
- ❑ Pad with count of pad size [ANSI X.923]
  - 1. E.g., [ b1 b2 b3 0 0 0 0 5] = 3 data, 5 pad w 1 count byte
- 1. A 1 bit followed by 0 bits [ISO/IEC 9797-1]
- 2. Any known byte value followed by zeros, e.g., 80-00...
- 3. Random data followed by count [ISO 10126]
  - 1. E.g., [b1 b2 b3 84 67 87 56 05]
- 4. Each byte indicates the number of padded bytes [PKCS]
  - 1. E.g., [b1 b2 b3 05 05 05 05 05]
- 5. **Self-Describing Padding** [RFC1570]
  - Each pad octet contains its index starting with 1
  - E.g., [b1 b2 b3 1 2 3 4 5]

Ref: [http://en.wikipedia.org/wiki/Padding\\_%28cryptography%29](http://en.wikipedia.org/wiki/Padding_%28cryptography%29)

# Cipher Text Stealing (CTS)

- ❑ Alternative to padding
- ❑ Last 2 blocks are specially coded
- ❑ Tail bits of (n-1)st encoded block are added to nth block and order of transmission of the two blocks is interchanged.

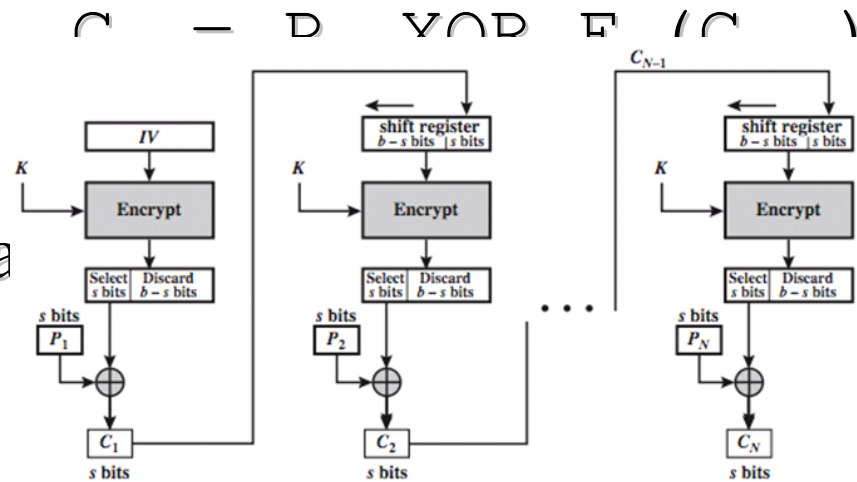

# Stream Modes of Operation

- ❑ Use block cipher as some form of **pseudo-random number** generator
- ❑ The random number bits are then XOR'ed with the message (as in stream cipher)
- ❑ Convert block cipher into stream cipher
  1. Cipher feedback (CFB) mode
  2. Output feedback (OFB) mode
  3. Counter (CTR) mode

# Cipher Feedback (CFB)

- ❑ Message is added to the output of the block cipher
- ❑ Result is feed back for next stage (hence name)
- ❑ Standard allows any number of bit (1, 8, 64 or 128 etc) to be feed back, denoted CFB-1, CFB-8, CFB-64, CFB-128 etc
- ❑ Most efficient to use all bits in block (64 or 128)

❑ Errors propa

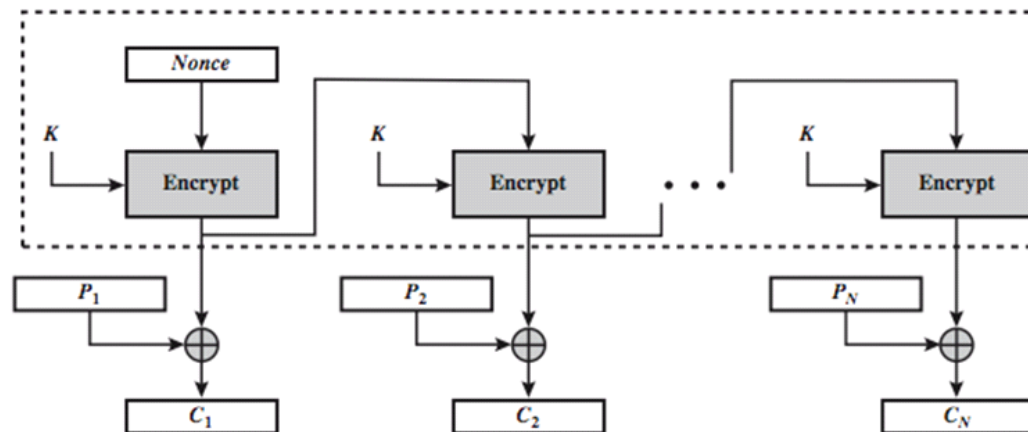

the error

# Output Feedback (OFB)

- ❑ Output of the cipher is feed back (hence name)
- ❑ Feedback is independent of message
- ❑ Can be computed in advance

$$O_i = E_K(O_{i-1})$$
$$C_i = P_i \text{ XOR } O_i$$
$$O_{-1} = IV$$

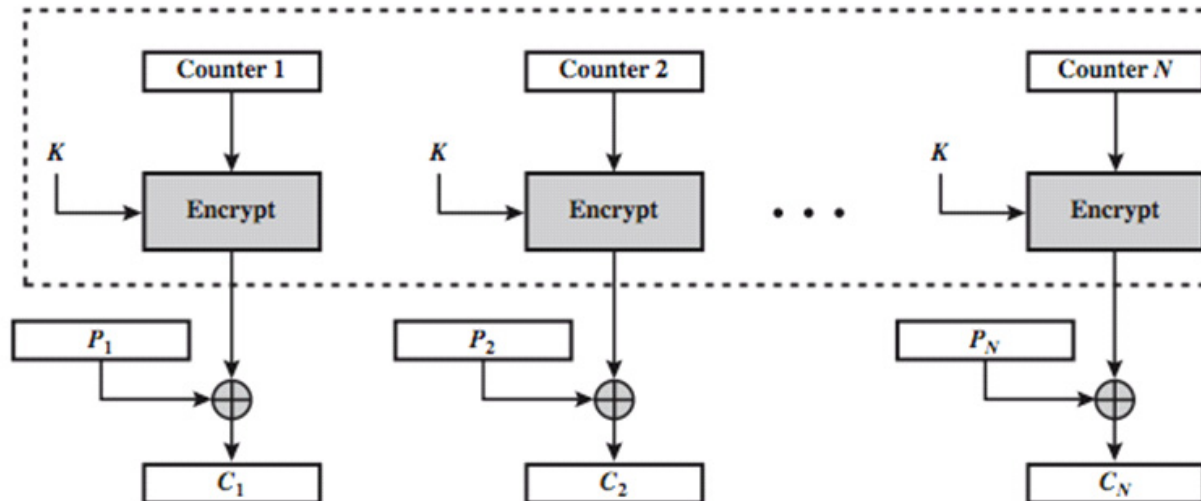

# Advantages and Limitations of OFB

- ❑ Needs an IV which is unique for each use
  - if ever reuse attacker can recover outputs
- ❑ Bit errors do not propagate
- ❑ More vulnerable to message stream modification
- ❑ Sender & receiver must remain in sync
- ❑ Only use with full block feedback
  - Subsequent research has shown that only **full block feedback** (i.e., CFB-64 or CFB-128) should ever be used

# Counter (CTR)

- ❑ Encrypt counter value rather than any feedback value
- ❑ Different key & counter value for every plaintext block (never reused)

$$O_i = E_K(i)$$
$$C_i = P_i \text{ XOR } O_i$$

# Advantages and Limitations of CTR

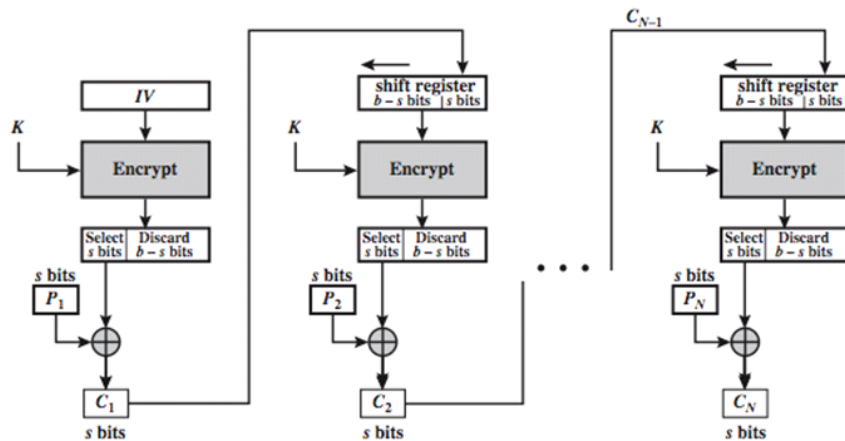

- ❑ Efficiency
  - Can do parallel encryptions in h/w or s/w
  - Can preprocess in advance of need
  - Good for bursty high speed links
- ❑ Random access to encrypted data blocks
- ❑ Provable security (good as other modes)
- ❑ But must never reuse key/counter values, otherwise could break

# Storage Encryption

- ❑ File encryption:
  - Different keys for different files
  - May not protect metadata, e.g., filename, creation date,
  - Individual files can be backed up
  - Encrypting File System (EFS) in NTFS provides this svc
- ❑ Disk encryption:
  - Single key for whole disk or separate keys for each partition
  - Master boot record (MBR) may or may not be encrypted
  - Boot partition may or may not be encrypted.
  - Operating system stores the key in the memory  
Can be read by an attacker by cold boot
- ❑ Trusted Platform Module (TPM): A secure coprocessor chip on the motherboard that can authenticate a device  
⇒ Disk can be read only on that system.  
Recovery is possible with a decryption password or token

# Storage Encryption (Cont)

- ❑ If IV is predictable, CBC is not usable in storage because the plain text is chosen by the writer
- ❑ Ciphertext is easily available to other users of the same disk
- ❑ Two messages with the first blocks  $=b \oplus IV_1$  and  $b \oplus IV_2$  will both encrypt to the same ciphertext
- ❑ Need to be able to read/write blocks without reading/writing other blocks

CBC

# XTS-AES Mode

- ❑ XTS = **X**EX-based **T**winked Codebook mode with Ciphertext **S**tealing (XEX = Xor-Encrypt-xor)

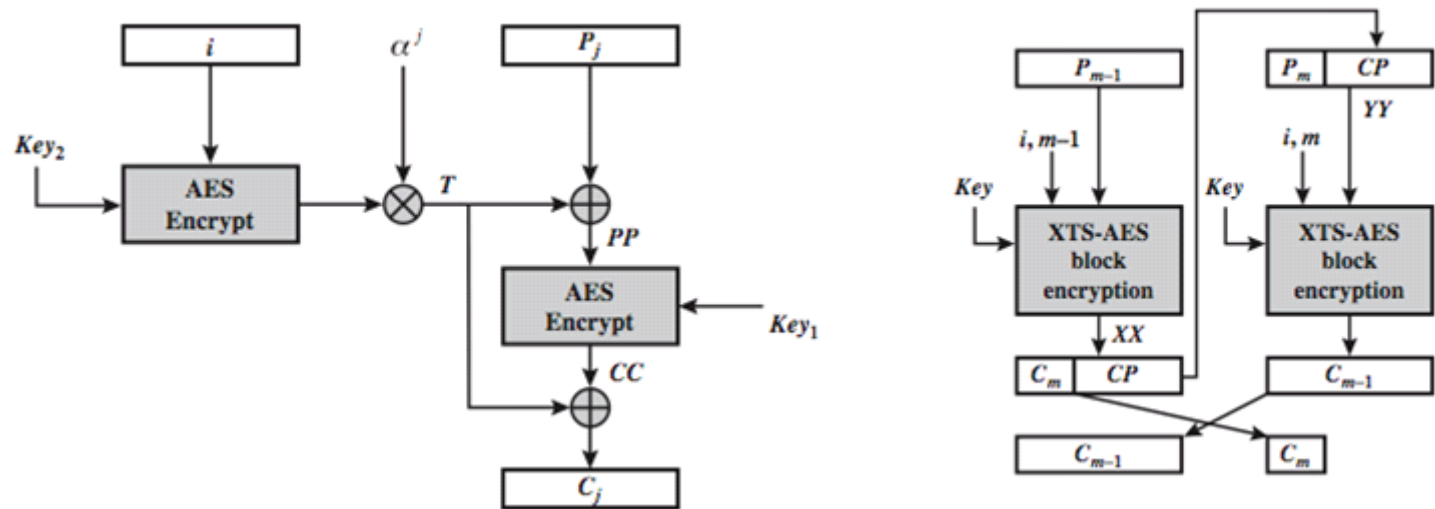

- ❑ Creates a unique IV for each block using AES and 2 keys

$$T_j = E_{K_2}(i) \otimes \alpha^j \quad \text{Size of } K_2 = \text{size of block}$$

$$C_j = E_{K_1}(P_j \oplus T_j) \oplus T_j \quad K_1 \text{ 256 bit for AES-256}$$

where  $i$  is logical sector # &  $j$  is block # (sector =  $n$  blocks)

$\alpha$  = primitive element in  $GF(2^{128})$  defined by polynomial  $x$

# Advantages and Limitations of XTS-AES

- ❑ Multiplication is modulo  $x^{128}+x^7+x^2+x+1$  in  $GF(2^{128})$
- ❑ Efficiency
  - Can do parallel encryptions in h/w or s/w
  - Random access to encrypted data blocks
- ❑ Has both nonce & counter
- ❑ Defined in IEEE Std 1619-2007 for block oriented storage use
- ❑ Implemented in numerous packages and operating systems including TrueCrypt, FreeBSD, and OpenBSD softraid disk encryption software (also native in Mac OSX Lion's FileVault), in hardware-based media encryption devices by the SPYRUS Hydra PC Digital Attaché and the Kingston DataTraveler 5000.

Ref: [http://en.wikipedia.org/wiki/Disk\\_encryption\\_theory](http://en.wikipedia.org/wiki/Disk_encryption_theory)

# Summary

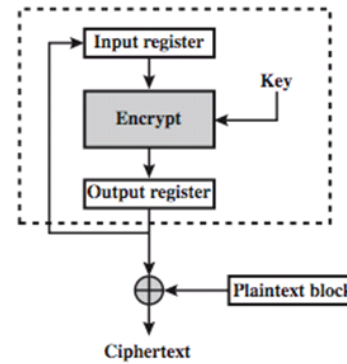

- ❑ 3DES generally uses E-D-E with 2 keys  $\Rightarrow$  112b protection
- ❑ ECB: Same ciphertext for the same plaintext  $\Rightarrow$  Easier to break

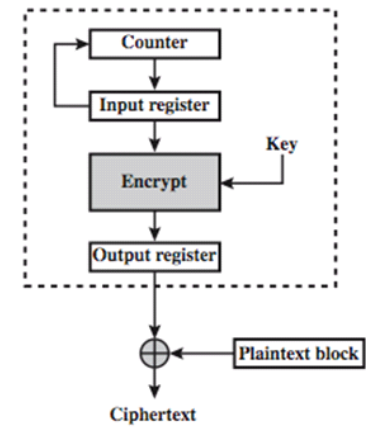

(a) Cipher block chaining (CBC) mode

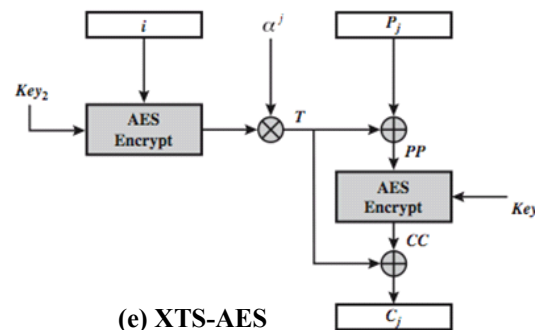

(b) Cipher feedback (CFB) mode

(c) Output feedback (OFB) mode

(d) Counter (CTR) mode

(e) XTS-AES

# Homework 6

**6.4** For each of the modes ECB, CBC and CTR:

- a. Identify whether decrypted plaintext block  $P_3$  will be corrupted if there is an error in block  $C_1$  of the transmitted cipher text.
- b. Assuming that the ciphertext contains  $N$  blocks, and that there was a bit error in the source version of  $P_1$ , identify through how many ciphertext blocks this error is propagated.
